# Land prices and unemployment comove over business cycles

# Negative shock to land price raises unemployment and lowers macro quantities

## ► Challenges

# What does this paper do?

- ▶ Provide a structural analysis of dynamic links between land prices and unemployment
- ▶ Show empirical relevance of this structural analysis
- ▶ Key features: incorporate labor search frictions and financial frictions in a unified DSGE framework to fit U.S. time series

# Challenges

- ▶ Theory: no obvious transmission mechanism to link land-price dynamics to unemployment fluctuations
  - ▶ Impaired balance sheets reduce consumption (Iacoviello 2005; Mian-Sufi 2012; Mian-Sufi-Rao 2013)
  - ▶ Drops in collateral value reduce business investment (Gan 2007; Chaney, et al. 2012; Liu-Wang-Zha 2013)
- ▶ Empirics: Hard to generate **large volatility** of labor market (Shimer 2005)
- ▶ Question: Can our structural model link land-price fluctuations to large volatility of unemployment?
  - ▶ Short answer: “Yes.” ▶ Styled facts

# Economic environment

- ▶ Households: patient
  - ▶ Some members employed, others not
  - ▶ All members consume goods and housing services
  - ▶ Provide loans
- ▶ Capitalists: impatient
  - ▶ Produce capital (investment) and consume goods
  - ▶ Borrow against collateral value (land and capital)
  - ▶ Own firms
- ▶ Firms: Produce final goods using labor, land, and capital as inputs
- ▶ Labor market: DMP search and matching frictions.

- ▶ Household family's utility function:

$$E \sum_{t=0}^{\infty} \beta_h^t \left[ \frac{(L_{ht}^{\varphi_{Lt}} (C_{ht} - \eta_h C_{ht-1}) / Z_t^p)^{1-\gamma}}{1-\gamma} - \chi g(h_t) N_t \right]$$

- ▶ Budget constraint

$$C_{ht} + \frac{B_{ht}}{R_t} + Q_{lt} (L_{ht} - L_{h,t-1}) = B_{ht-1} + W_t h_t N_t + b Z_t^p (1 - N_t) - T_t.$$

- ▶ Important features:

- ▶ Housing demand shock ( $\varphi_{Lt}$ ): main source of land-price fluctuations (Iacoviello-Neri, 2010; Liu-Wang-Zha, 2013)
- ▶ Non-separable utility: muted wage responses to housing demand shocks and large labor-market volatility

# Capitalists

- ▶ Utility function:

$$E \sum_{t=0}^{\infty} \beta_c^t \ln (C_{ct} - \eta_c C_{ct-1}), \quad \beta_c < \beta_h$$

- ▶ Flow-of-funds constraint:

$$C_{ct} + Q_{lt} (L_{ct} - L_{c,t-1}) + I_t + \Phi(e_t) K_{t-1} + B_{c,t-1} = \frac{B_{ct}}{R_t} + R_{kt} e_t K_{t-1} + R_{lt} L_{c,t-1} + \Pi_t.$$

- ▶ Collateral constraint:

$$B_{ct} \leq \xi_t E_t (\omega_1 Q_{l,t+1} L_{ct} + \omega_2 Q_{k,t+1} K_t),$$

- ▶ Capital law of motion:

$$K_t = (1 - \delta) K_{t-1} + \left[ 1 - \frac{\Omega}{2} \left( \frac{I_t}{I_{t-1}} - \bar{\gamma}_I \right)^2 \right] I_t.$$

- ▶ Matching function:

$$m_t = \varphi m_t u_t^a v_t^{1-a},$$

- ▶ Employment dynamics:

$$N_t = (1 - \rho) N_{t-1} + m_t.$$

- ▶ Searching workers:

$$u_t = 1 - (1 - \rho) N_{t-1}.$$

- ▶ Unemployment rate:

$$U_t = u_t - m_t = 1 - N_t.$$

- ▶ Production function:

$$y_t = Z_t^{1-\alpha+\phi\alpha} \left( l_{ct}^\phi k_t^{1-\phi} \right)^\alpha h_t^{1-\alpha}.$$

- ▶ Match value:

$$J_t^F = \max_{k_t, l_{ct}} \pi_t - W_t h_t + E_t \frac{\beta_c \Lambda_{ct+1}}{\Lambda_{ct}} \left[ (1 - \rho) J_{t+1}^F + \rho V_{t+1} \right],$$

where  $\pi_t = y_t - R_{kt} k_t - R_{lt} l_{ct}$ .

- ▶ Vacancy value:

$$V_t = -\kappa Z_t^P + q_t^v J_t^F + (1 - q_t^v) E_t \frac{\beta_c \Lambda_{c,t+1}}{\Lambda_{ct}} V_{t+1}$$

- ▶ Free entry:  $V_t = 0 \Rightarrow$

$$\frac{\kappa Z_t^P}{q_t^v} = J_t^F$$

# Worker value functions and Nash bargaining

- ▶ Value of employment:

$$J_t^W = W_t h_t - \frac{\chi g(h_t)}{\Lambda_{ht}} + E_t \frac{\beta_h \Lambda_{h,t+1}}{\Lambda_{ht}} \left[ (1 - \rho(1 - q_{t+1}^u)) J_{t+1}^W + \rho(1 - q_{t+1}^u) J_{t+1}^U \right].$$

- ▶ Value of unemployment:

$$J_t^U = bZ_t^p + E_t \frac{\beta_h \Lambda_{h,t+1}}{\Lambda_{ht}} \left[ q_{t+1}^u J_{t+1}^W + (1 - q_{t+1}^u) J_{t+1}^U \right].$$

- ▶ Nash bargaining problem:

$$\max_{W_t, h_t} \left( J_t^W - J_t^U \right)^{\frac{\vartheta_t}{1+\vartheta_t}} \left( J_t^F - V_t \right)^{\frac{1}{1+\vartheta_t}},$$

# Government policy and market clearing conditions

- ▶ Government budget

$$bZ_t^p(1 - N_t) = T_t.$$

- ▶ Goods market clearing

$$C_t + I_t + \Phi(e_t)K_{t-1} + \kappa Z_t^p v_t = Y_t.$$

- ▶ Aggregate output

$$Y_t = \left[ (Z_t L_{c,t-1})^\phi (e_t K_{t-1})^{1-\phi} \right]^\alpha (Z_t h_t N_t)^{1-\alpha}.$$

- ▶ Housing market clearing

$$L_{ct} + L_{ht} = \bar{L}.$$

- ▶ Bond market clearing

$$B_{ct} = B_{ht} \equiv B_t.$$

- ▶ Capital market clearing

$$e_t K_{t-1} = N_t k_t.$$

# Quarterly time series data from 1976:Q1-2013:Q1

1. Land price: Constructed from CoreLogic house price based on Davis-Heathcote (2007) approach
2. Consumption: Real per capita consumption of nondurables and non-housing services.
3. Investment: Real per capita business investment (consumer durable plus investment in equipment and intellectual property).
4. Labor hours: total hours in nonfarm business sector.
5. Vacancy rate: Combining JOLTS (post 2001) and Barnichon (2010) help-wanted index (pre-2001)
6. Unemployment rate

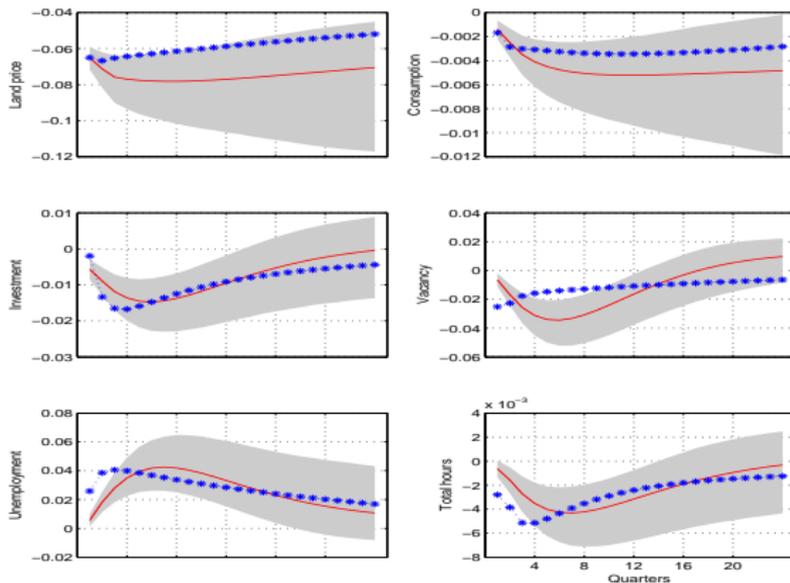

# Estimation strategy

- (1) Calibrate several steady state ratios and a subset of parameters ▶ Calibration
- (2) Estimate parameters that do not affect steady state, including habit, adjustment costs, utilization rate, and shock processes  
▶ Structural parameters ▶ Shock parameters
- (3) Given (1) and (2), obtain remaining parameters using steady-state restrictions — a recursive procedure.

# Estimation results

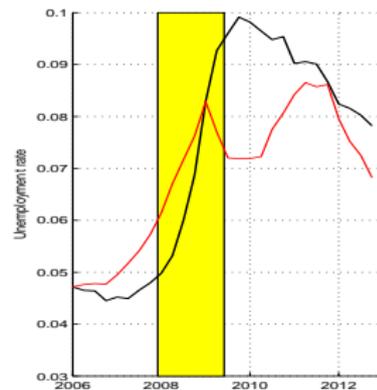

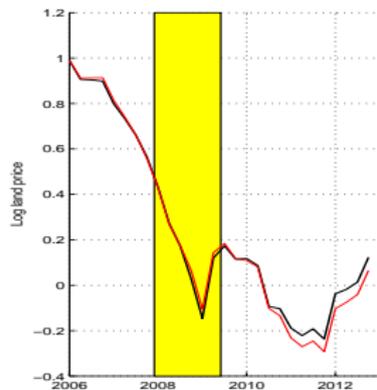

- ▶ Land price fluctuations primarily driven by housing demand shocks
- ▶ Model fits data well along both dimensions: comovement and volatility
  - ▶ Comovement
    - ▶ A 10% drop in land price  $\Rightarrow$  unemployment rises by 0.34 percentage points (relative to ss)
- ▶ Great Recession: housing demand accounts for 2.5 percentage point increases in unemployment
  - ▶ Great Recession
- ▶ Model generates Shimer's (2005) volatility ratio: std of labor-market tightness relative to that of labor productivity
  - ▶ Shimer ratio = 27.47 in simulated data from estimated model (compared to 24.91 in actual data)

# Land price and unemployment: data vs model

# Great Recession

## ► Estimation results

# Transmission mechanism

- ▶ Credit channel: land price and unemployment comove (through collateral constraints)
- ▶ Labor channel: effects of housing demand shocks on unemployment amplified (non-separable preferences)

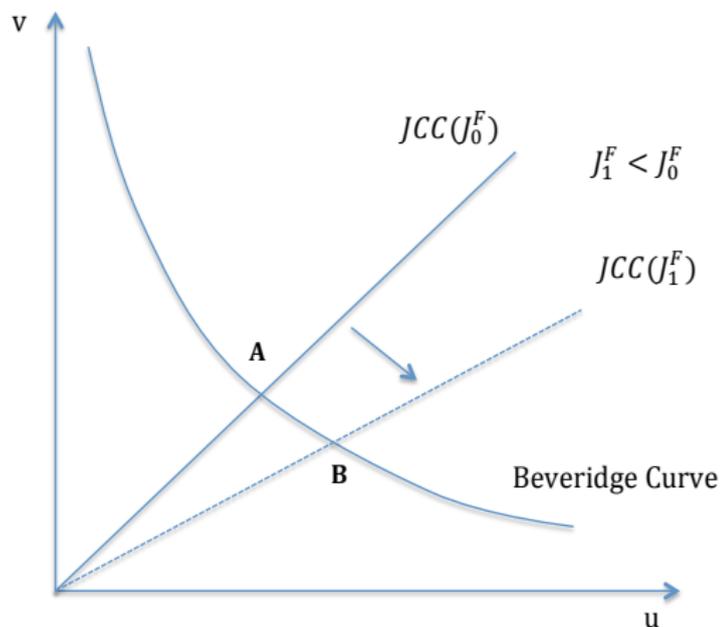

$$J_t^F = F(k_t, l_t, h_t) - W_t h_t + E_t \frac{\beta_c \Lambda_{ct+1}}{\Lambda_{ct}} (1 - \rho) J_{t+1}^F$$

A negative housing demand shock

- fall of land price and tightened borrowing capacity
- reductions in business investment and land acquisition (further depressing land price)
- lower current investment leads to lower future  $K$
- reduced future marginal product of workers
- fall of PV of new match (for any given  $W$  and  $h$ )
- fewer vacancies posting
- lower job finding rate and higher  $U$
- reduced household income
- further reductions in housing demand and land price

# Transmission through credit channel with search frictions

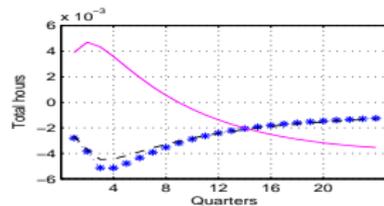

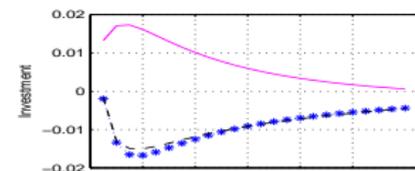

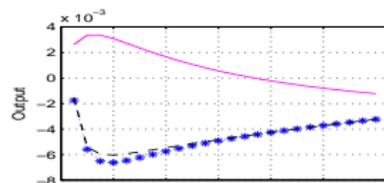

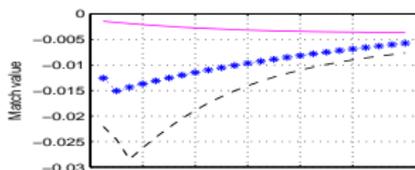

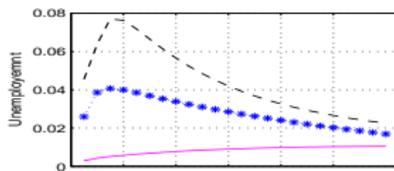

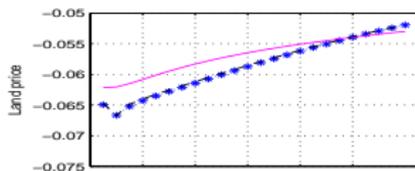

- ▶ Beveridge curve (BC):  $\rho(1 - u) = \varphi_m u^a v^{1-a}$
- ▶ Job creation curve (JCC):  $\frac{\kappa}{q^v} = J^F$

# Importance of credit channel

- ▶ Consider a counterfactual economy with constant debt limit for capitalists
- ▶ Declines in land price have no effect on borrowing capacity
- ▶ Lower land price free up resources for investment spending
  - land price and consumption fall, while investment, output and hours rise —no comovement
  - Muted impact of housing demand shock on match value and unemployment —small volatility

# No credit channel (solid lines)

# Labor channel

- ▶ Declines in land price reduce investment and hiring through credit channel
- ▶ But drop in wages can blunt the impact of the shock on labor market (Shimer, 2005)
- ▶ Labor channel: non-separable preferences  $\rightarrow$  endogenous wage rigidities

▶ Technology shock

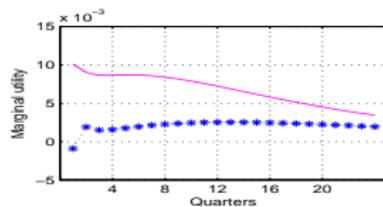

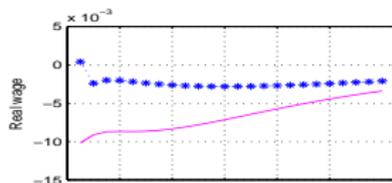

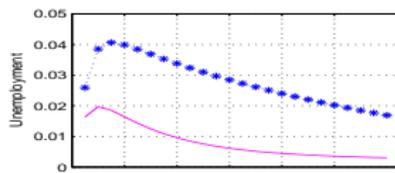

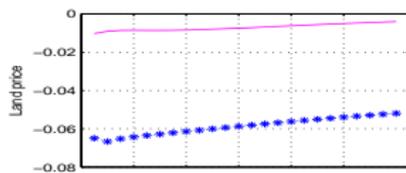

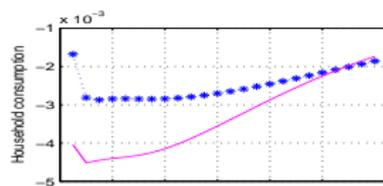

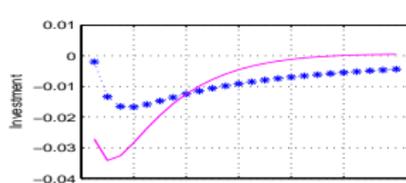

# The labor channel and endogenous wage rigidities

- ▶ Nash bargained wage equation:

$$w_t = \frac{\chi g(h_t)/h_t}{\Lambda_{ht}} + bZ_t^p/h_t + \frac{1}{h_t} \left[ \vartheta_t J_t^F - E_t \frac{\beta_h \Lambda_{h,t+1}}{\Lambda_{ht}} \left( (1-\rho)(1-q_{t+1}^u) \vartheta_{t+1} J_{t+1}^F \right) \right].$$

- ▶ Technology shock: muted impact on unemployment because wage declines
  - ▶ Tech shock reduces match value and vacancy postings, prolongs unemployment duration ( $1/q^u$ )  $\rightarrow$  wage falls
  - ▶ Tech shock also lowers consumption and raises marginal utility  $\rightarrow$  further declines in wage
- ▶ Housing demand shock: large impact on unemployment because wage is endogenously rigid
  - ▶ Non-separable utility  $\rightarrow$  housing demand shock directly lowers marginal utility ( $\Lambda_{ht}$ )  $\rightarrow$  offsetting downward pressures on wage

# Housing demand shock vs. technology shock

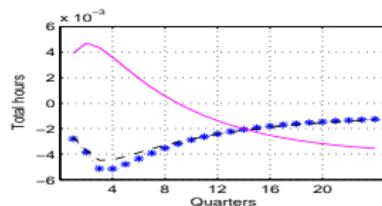

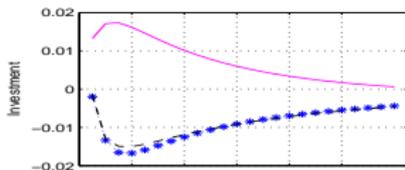

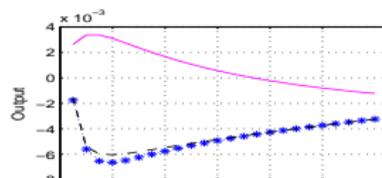

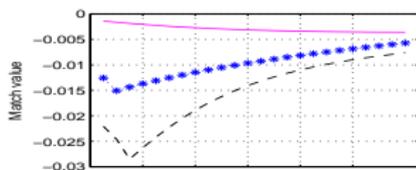

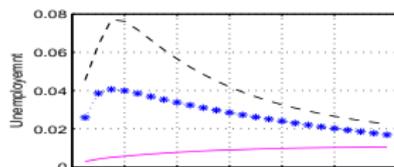

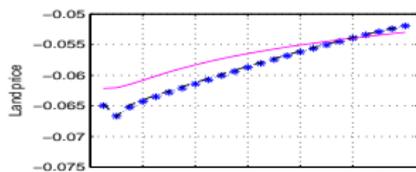

# Intensive margin important

- ▶ Counterfactual: inelastic supply of labor hours (no intensive margin)
- ▶ Match value falls more than that in estimated model because firms cannot cut costs by reducing hours
- ▶ Overshooting of unemployment dynamics

▶ InelasticLaborHours

# Inelastic hours for employed worker (dashed lines)

# Conclusion

- ▶ Credit channel and labor channel reinforce each other to transmit fluctuations in land price into
  - ▶ persistent movement in unemployment
  - ▶ and large volatility of the labor market
- ▶ Persistence and volatility are both large enough to be consistent with U.S. data.
- ▶ DSGE framework provides essential ingredients for further research on interactions between housing market and labor market over the business cycle

# Structural parameters: Calibrated

Parameter	Description	value
$a$	Share parameter in match function	0.50
$b/W$	Replacement ratio	0.75
$\alpha$	Capital income share	0.33
$\gamma$	Risk aversion for household	2
$\rho$	Job separation rate	0.12
$U$	Unemployment rate	5.5%

Consistent with Kocherlakota (1996), Lucas Jr. (2003), Hall and Milgrom (2008), Blanchard and Galí (2010), Christiano, Eichenbaum, and Trabandt (2013). [▶ Back to estimation strategy](#)
